References

This is model to estimate the probability of ruin in continuous and finite time for a compound Poisson risk process where the premium rate is constant throughout each year but can change at the start of each year. This method was developed by [Afonso et al., 2009] for large portfolios. General references are text by [Seal, 1969], [Bühlmann, 1970], [Gerber, 1979], [Bowers et al., 1997] or more recently [Asmussen, 2000].

Evaluate (numerically) the ruin probability in continuous and finite time for a Compound Poisson risk process

Assumptions:

- The occurrence of claims is a Poisson Process.
- The premium is received at a constant rate during each year, but may change every year.

# Definitions

We consider a risk process over an  $n$ -year period. We denote by  $S(t)$  the aggregate claims up to time  $t$ , so that  $S(0) = 0$ , and by  $Y_i$  the aggregate claims in year  $i$ ,  $i = 1, \dots, n$ , so that  $Y_i = S(i) - S(i - 1)$ . We assume that  $\{Y_i\}_{i=1}^n$  is a sequence of *i.i.d.* random variables, each with a compound Poisson distribution whose first three moments exist. We denote by  $\lambda$  the Poisson parameter for the expected number of claims each year and by  $f(s)$  the probability density function (*pdf*) of  $S(s)$  for  $0 < s \leq 1$ .

# Definitions

Let  $P_i$  denote the premium charged in year  $i$  and let  $U(t)$  denote the insurer's surplus at time  $t$ ,  $0 \leq t \leq n$ . We assume premiums are received continuously at a constant rate throughout each year. The initial surplus,  $u (= U(0))$ , and the initial premium,  $P_1$ , are known. For any time  $t$ ,  $0 \leq t \leq n$ ,  $U(t)$  is calculated as follows:

$$U(t) = u + \sum_{j=1}^{i-1} P_j + (t - i + 1)P_i - S(t)$$

where  $i$  is the integer such that  $t \in [i - 1, i[$ , and where  $\sum_{j=1}^0 P_j = 0$ .

# Definitions

For  $i \geq 2$ , the premium  $P_i$  and surplus level  $U(i)$  are random variables since they both depend on the claims experience in previous years. Where we wish to refer to a particular realization of these variables, we will use the lower case letters  $p_i$  and  $u(i)$ , respectively. The probability of ruin in continuous time within  $n$  years is denoted by  $\psi(u, n)$  and defined as follows:

$$\psi(u, n) \stackrel{\text{def}}{=} \Pr(U(t) < 0 \text{ for some } t \in ]0, n])$$

Figure: Sample path of surplus

# Inputs

Figure 2 shows the inputs needed to the simulation procedure. The **Initial surplus** is the available amount of surplus for the portfolio. **Expected premiums received during the next 4 years** are the expected amounts to be received in the next years. The method also needs the first moment of the Poisson process. **Random seed from 1 to 1000** allows you to choose a different seed for the simulation procedure in order to obtain the same result on the next simulation.

Initial surplus			
<input type="text" value="100000.0"/>			
Expected premiums received during the next 4 years			
<input type="text" value="7.0E7"/>	<input type="text" value="6.5E7"/>	<input type="text" value="6.0E7"/>	<input type="text" value="5.5E7"/>
Moments		No. Of Claims (N)	Amount of individual claims (X)
Expected value	<input type="text" value="30000.0"/>	<input type="text" value="2000.0"/>	
Variance	<input type="text" value="1600000"/>		
Third central moment	<input type="text" value="1000000000"/>		
Random seed from 1 to 1000			
<input type="text" value="1000"/>			
<input type="button" value="Calculate"/>			

Figure: Inputs

# Outputs

Figure 3 shows the path of the premiums, the expected path of claims and surplus. The bar indicates the evolution of the 1.000 runs of the simulation procedure.

Figure: Expected path of the surplus

# Outputs

Figure 4 shows the results of the simulation. It indicates the average and the variance of the 1.000 runs that estimate  $\psi(u, 2)$  and  $\psi(u, 4)$ . In this case as the expected path for the surplus decreases from year 2 forward  $\psi(u, 2) < \psi(u, 4)$ .  $\psi(100.000, 2) = 0,0785$  means that the probability of ruin in two years time with an initial surplus of 100.000 in the portfolio described in Figure 2 is 7,85%.  $\psi(100.000, 4) = 51,7\%$ . One should increase the surplus during the year 3 or the premiums in order to decrease the probability of ruin.

	Average	Variance
Ruin probability during 2 years horizon	7,84669e-2	4,37187e-7
Ruin probability during 4 years horizon	5,16765e-1	2,14597e-4

New simulation

Figure: Results of the simulation

# Other Results

- If the claim number is not a Poisson Process, for example in Automobile portfolio in the presence of a Bonus Malus System (BMS), this method does not apply. The model has to be adjusted.
- Compare the impact on the ruin probabilities of different BMS.
- Evaluate the ruin probabilities of a Automobile portfolio in the classical model (closed portfolio) and using stochastic vortices (open portfolio).
- Compute any within the year ruin probability and the ultimate ruin probability for the portfolio.
- Change the claim amount distribution during the time horizon.
